## Model based approaches

### Reminder on Supervised Learning

- $\blacktriangleright$ input data  $X \in \mathbb{R}^p$
- ightharpoonup reponse Y to be predicted
- training set  $(X_1, Y_1), \ldots, (X_n, Y_n)$

#### Discriminative models

Direct learning of P(Y|X), e.g. generalized linear models s.t.

- ▶ Linear regression
- ► Logistic regression (← classification tasks)
- ▶ ...

## Linear Regression Problem

- ▶  $X_i = (X_{i,1}, \dots, X_{i,p})^T \in \mathbb{R}^p$ , ▶  $Y_i \in \mathbb{R}$ . for  $i = 1, \dots, n$  (sized n training set)
- Linear Regression Model

$$Y_i = \beta_0 + \sum_{j=1}^p \beta_j X_{i,j} + \sigma \epsilon_i, \quad \text{for } i = 1, \dots, n,$$

- ▶  $\epsilon_i$  is a centered with unit variance  $(E[\epsilon_i] = 0, \text{ var } (\epsilon_i) = 1)$  white noise
- $\triangleright$   $\beta_0$  is the "intercept" (reduces to the ordinate at the origin when p=1)
- $\beta \equiv (\beta_0, \dots, \beta_p) \in \mathbb{R}^{p+1}$  is the coefficient vector

Objective : estimation of  $\beta \leftarrow$  supervised learning problem

## Linear Regression Problem (Cont'd)

### Linear Regression Model

$$Y_i = \beta_0 + \sum_{j=1}^p \beta_j X_{i,j} + \sigma \epsilon_i, \quad \text{for } i = 1, \dots, n,$$

Remark : model linear w.r.t.  $\beta \equiv (\beta_0, \dots, \beta_p) \in \mathbb{R}^{p+1}$  , but not necessarily linear w.r.t.

- ▶ the inputs  $X_i$ : we can add non linear predictors  $h(X_1, ..., X_p)$  in the model, e.g.  $X_i^2, X_i X_j$ ...
- ▶ the outputs  $Y_i$ : we can introduce a non linear link function  $\leftarrow$  generalized linear model, e.g. logistic regression

## Linear model: Keep it simple!

Simple linear approach may seem overly simplistic

- true regression functions are never linear
- + extremly useful, both conceptually and practically

### Practically

Gorge Box, 60': "Essentially, all models are wrong, but some are very useful"

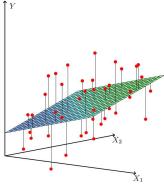

Simple is actually very good: works very well in a lot of situations by capturing the main effects (which are generally the most interesting)

### Conceptually

Many concepts developed for the linear problem are important for a lot of the supervised learning techniques

Although it is nerver correct, a linear model serves as a good and interpretable approximation of the unknown true function f(X)

## Least Squares (LS) Estimator

Linear least squares fitting with  $X \in \mathbb{R}^2$ 

LS estimate defined by minimizing the Residual Sum of Squares (RSS)

$$\widehat{\beta} = \arg\min_{\beta} \underbrace{\sum_{i=1}^{n} \left( y_i - \beta_0 - \sum_{j=1}^{p} \beta_j x_{i,j} \right)^2}_{\text{RSS}(\beta)}$$

▶ RSS( $\beta$ )  $\propto$  training error rate for quadratic loss

## Least Squares Estimator (Cont'd)

$$\widehat{\beta} = \arg\min_{\beta} \text{RSS}(\beta), \text{ where } \text{RSS}(\beta) = \sum_{i=1}^{n} \left( y_i - \beta_0 - \sum_{j=1}^{p} \beta_j x_{i,j} \right)^2$$

### Matrix expression of RSS

$$RSS(\beta) = ||Y - X\beta||_2^2,$$

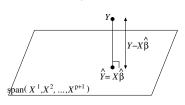

where 
$$Y = \begin{pmatrix} y_1 \\ \vdots \\ y_n \end{pmatrix} \in \mathbb{R}^n$$
,  $X = \begin{pmatrix} 1 & x_{1,1} & \dots & x_{1,p} \\ \vdots & \vdots & & \vdots \\ 1 & x_{n,1} & \dots & x_{n,p} \end{pmatrix} \in \mathbb{R}^{n \times (p+1)}$ 

### LS Estimator derivation

 $\widehat{Y}=X\widehat{\beta}$  is the prediction in the space spanned by the column vectors of X such that the euclidean error norm  $||Y-X\widehat{\beta}||_2$  is minimized

### Orthogonality principle

Let  $X^j$  be the jth column of X

for 
$$j = 1, ..., p + 1$$
  

$$\langle X^j, Y - X\widehat{\beta} \rangle = (X^j)^T \left( Y - X\widehat{\beta} \right) = 0,$$

$$\Leftrightarrow X^T \left( Y - X\widehat{\beta} \right) = 0,$$

$$\Leftrightarrow \left( X^T X \right) \widehat{\beta} = X^T Y$$

## LS Estimator computation

Assumption : rank X = p + 1, hence  $X^T X$  is invertible

Analytical expression

$$\widehat{\beta} = \left( X^T X \right)^{-1} X^T Y,$$

### Numerical computation in high dimension

When  $p>10^3$  or  $p>10^4$ , too expansive to compute  $\left(X^TX\right)^{-1}$  ... More efficient to use a numerical procedure to minimize the criterion  $J(\beta)\equiv \frac{1}{2}\mathrm{RSS}(\beta)$ , e.g. steepest descent

$$\beta_{k+1} = \beta_k - \alpha_k \nabla_\beta \ J(\beta_k),$$

where step size  $\alpha_k \in \mathbb{R}$  is the *learning rate*, and descent direction is computed as

- ▶ batch gradient  $\nabla_{\beta} J(\beta) = X^T X \beta X^T Y$
- ▶ stochastic gradient  $\nabla_{\beta} J(\beta) \approx X_i^T X_i \beta X_i^T Y_i$  for  $i = 1, \ldots, n$  (scan of the training set) ← cheaper than batch one for a single iteration
- mini-batch gradient : tradeoff between batch and stochastic gradients

## Linear model for classification: Logistic regression

Classification problem  $Y \in \mathcal{Y} \leftarrow$  discrete set

Binary classification problem :  $\mathcal{Y} = \{1, 2\}$ 

Consider the following model

$$\Pr(Y_i = 1 | X_i = x_i) = \phi(x_i^T \beta) = \frac{\exp(x_i^T \beta)}{1 + \exp(x_i^T \beta)},$$

where

- $x_i = (1, x_{i,1}, \dots, x_{i,p})^T \in \mathbb{R}^{p+1} \leftarrow \text{intercept term included by default,}$
- $\phi: u \in \mathbb{R} \mapsto \frac{\exp(u)}{1+\exp(u)} \in (0,1)$  is the logistic function: maps a real value to a probability

## Logistic function

$$\phi(x) : \mathbb{R} \to ]0, 1[$$

$$u \mapsto \frac{\exp u}{1 + \exp u} = \frac{1}{1 + \exp(-u)}.$$

## Logit link function

#### Consider

- $p_i \equiv \Pr(Y_i = 1 | X_i = x_i) = \phi(x_i^T \beta)$
- $\phi^{-1}: p \in (0,1) \mapsto \log \frac{p}{1-p} \in \mathbb{R}$  is the logit function

#### Generalized linear model

▶ Linear equation w.r.t.  $\beta$ ,

$$logit (p_i) = x_i^T \beta,$$

additional nonlinear constraint :

$$\Pr(Y_i = 2 | X_i = x_i) = 1 - \underbrace{\Pr(Y_i = 1 | X_i = x_i)}_{p_i} = \frac{1}{1 + \exp(x_i^T \beta)}$$

Maximum Likelihood Estimates

$$\widehat{\beta} = \arg\min_{\beta} -\ell(\beta)$$

where  $\ell(\beta)$  is the log-likelihood (here logistic, but normal model yields LSE for linear regression)

## Outline

#### Linear Models

Linear regression Linear model for classification : Logistic regression

#### Model Validation

Cross-Validation Information Criterion

#### Model Selection

Subset selection
Regularization and shrinkage methods
Ridge regression
Lasso estimator

#### Applications

prostate data Heart diseases data

### Limitations of LS estimator

#### Problem

when rank  $X , or when X has singular values close to zero, then <math>X^T X$  is no more invertible, or ill conditioned (eigenvalues close to zero)...

#### Causes

- ▶ redundant or nearly-collinear predictors, e.g.  $X^k \approx aX^l + b$ , where  $X^j$  is the jth column of X
- ▶ high dimensional problem where  $p \approx n$  (or p > n)

#### Effects

no single, or stable, solution for  $\widehat{\beta}$ 

- ▶ high variance of  $\widehat{\beta}$  as an eigenvalue  $\lambda_i$  of  $X^TX$  is close to zero  $(||\widehat{\beta}|| \to +\infty$  as  $\lambda_i \to 0)$ ,
- ▶ true error rate explodes since a small perturbation in the training set yields a substantially different estimate  $\hat{\beta}$  and prediction rule  $\hat{y} = x^T \hat{\beta}$
- over-fitting problem

### Instability of LSE: Deconvolution illustration

- $y \in \mathbb{R}^n$  with  $n = 256^2$ ,  $\beta \in \mathbb{R}^p$  with  $p = 256^2$ ,
- ▶  $X \in \mathbb{R}^{n \times p} \leftarrow \text{sized } (256^2) \times (256^2) \text{ matrix...}$

 $\beta \leftarrow \text{original image}$ 

 $y = X\beta \leftarrow \text{blurred image}$ 

## Instability of LSE: Deconvolution illustration

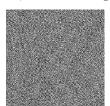

- $y \in \mathbb{R}^n$  with  $n = 256^2$ ,  $\beta \in \mathbb{R}^p$  with  $p = 256^2$ ,
- ▶  $X \in \mathbb{R}^{n \times p} \leftarrow \text{sized } (256^2) \times (256^2) \text{ matrix...}$

 $\beta \leftarrow \text{original image}$ 

 $y = X\beta \leftarrow \text{blurred image}$ 

 $\widehat{\beta} = (X^T X)^{-1} X^T y \leftarrow \text{LS estimate}$ 

### Reminder on Train and Test Errors

- ▶ Loss-function
  - ▶ Classification :  $L(y, \hat{y}) = 0$  if  $y = \hat{y}$  else  $1 \leftarrow 0$ -1 loss ▶ Regression :  $L(y, \hat{y}) = (y \hat{y})^2 \leftarrow$  quadratic loss
- ▶ Train error : average loss over the training sample

$$Err_{train} = \frac{1}{n} \sum_{i=1}^{n} L(y_i, \hat{y}_i)$$

- ightharpoonup Test/Prediction error: average loss over a new test sample ightharpoonupGeneralization error
- ▶ General picture :

$$\text{Err}_{\text{test}} \approx \text{Err}_{\text{train}} + O$$

O would be the average optimism (overfitting problem!)

∟<sub>Cross-Validation</sub>

### Model Validation

### Objective

Estimate the generalization error, i.e. the predictive performance, on unseen/test data

### Common Applications

- ▶ Hyperparameter tuning : estimate the best set of hyperparameters
- ▶ Model selection : estimate the performance of differents models

## Validation procedures

#### Validation set

Create a validation set, i.e. fresh data not used during the training set, to estimate the predictive performances/test error rate

- ▶ Best solution : collect a large data set of new test data... But in practice, this is generally not available/possible!
- ► Simple solution: split the data set. One part is removed from the training set and will be kept as a validation set only

#### But.

- only part of the data is used to train the model (introduces a bias)
- the role of the data is not symmetrical: some are used only for training, others only for testing (increases the variance)
- ▶ standard solution : cross-validation, e.g. K-fold Cross-Validation

## K-fold Cross-Validation (CV): Principle

▶ Based on splitting the data in K-folds, here K = 5:

$\operatorname{Err}_1(f_1,\lambda)$	Validation	Train	Train	Train	Train
$\mathrm{Err}_2(\hat{f}_2,\lambda)$	Train	Validation	Train	Train	Train
$\operatorname{Err}_3(\hat{f}_3,\lambda)$	Train	Train	Validation	Train	Train
$\mathrm{Err}_4(\hat{f}_4,\lambda)$	Train	Train	Train	Validation	Train
$\mathrm{Err}_5(\hat{f}_5,\lambda)$	Train	Train	Train	Train	Validation

where  $\lambda$  are some hyperparameters of the model/method

Estimate of Test error :

$$CV(\hat{f}, \lambda) = \frac{1}{K} \sum_{k=1}^{K} Err_k(\hat{f}_k, \lambda)$$

 ${\bf R}{\bf k}$  : built-in functions to make cross-validation are available in all ML/statistics softwares (Python,Matlab,R,...)

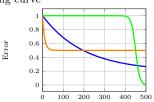

### Practical advices

How to choose the number of folds K?

 Bias/variance trade-off for the estimator of prediction performance/test error rate

	Bias	Variance
K low	High	Low
K high	Low	High
K = n	Low	Very High

▶ Be careful to the learning curve

Number of samples

- Usually K = 5 or 10 is a good trade-off (K = n is called 'leave-one-out')
- Be careful: Model should be trained completely for each fold (i.e., data normalization, optimization, etc...)

### Information Criterion

### Penalized log-likelihood criterion

$$C(K) = -\hat{\ell}(x; \lambda) + \text{pen}(\lambda, n)$$

- $\hat{\ell}(x;\lambda) \equiv \ell(x;\hat{\beta}_{\lambda})$  with  $\hat{\beta}_{\lambda}$  the MLE of the model parameters
- $\hat{\ell}(x;\lambda) \propto \text{RSS}(\hat{\beta}_{\lambda})$  for linear regression (normal model)
- $ightharpoonup \lambda$  are the hyperparameters of the model that drive its complexity (e.g. number k of variables that enter in the model)

Trade-off between two terms (to minimize)

- $-\hat{\ell}(x;\lambda)$ : fidelity to the data (likelihood)
- ▶  $pen(\lambda, n)$ : low complexity of the model

## Bayesian Information Criterion (BIC)

Asymptotic  $(n\gg k_\lambda)$  criterion for Bayesian models (i.e. with a prior on the model parameters)

$$pen(k_{\lambda}, n) = \frac{1}{2}k_{\lambda}\log(n)$$

- $\triangleright$  n is the size of the dataset
- $k_{\lambda}$  is the effective number of parameters for the  $\lambda$  hyperparameter

$$BIC(\lambda) = -2\hat{\ell}(x;\lambda) + k_{\lambda}\log(n)$$

- Model comparison : select model  $\hat{\ell}_j(x;\lambda_j)$  with minimal BIC
- BIC Hyperparmeter tuning: choose value  $\hat{\lambda}$  that minimizes BIC

## Akaïke Information Criterion (AIC)

Other popular asymptotic  $(n \gg k_{\lambda})$  criterion

$$AIC(\lambda) = -2\hat{\ell}(x;\lambda) + 2k_{\lambda}$$

- $\triangleright$   $k_{\lambda}$  is the effective number of parameters for the  $\lambda$  hyperparameter
- ▶ Comparison with BIC :  $\log(n) k_{\lambda}$  replaced by  $2 k_{\lambda}$
- Variant less aggressive (as long as  $\log(n) > 2$ , where n is the sample size)

### Outline

#### Linear Models

Linear regression Linear model for classification : Logistic regression

#### Model Validation

Cross-Validation Information Criterion

#### Model Selection

Subset selection Regularization and shrinkage methods

Ridge regression Lasso estimator

#### Applications

prostate data Heart diseases data

### Subset selection

#### Motivation

- ▶ interpretation : with a large number of predictors, we often would like to determine a smaller subset that exhibit the main (strongest) effects.
- prediction accuracy: can always be improved by shrinking or setting some coefficients to zero, thus preventing from overfitting

### Principle

- ▶ Retain only a subset of the variables, and eliminate the rest from the model
- different strategies for choosing the subset

## Forward-stepwise selection

Greedy algorithm producing an increasing nested sequence of models:

- starts with the intercept
- $\blacktriangleright$  then sequentially adds into the model the predictor that most improves the fit

Produces a sequence of models indexed by k, the subset size, which must be determined.

choosing k? cross-validation, AIC/BIC, 'significance' criterion, ...

#### Remarks

- ▶ suboptimal procedure, but we can always compute the forward stepwise sequence (even when  $p \gg n$ )
- ▶ similar to *orthogonal matching pursuit* in signal processing

## Backward-stepwise selection

Greedy algorithm producing a decreasing nested sequence of models:

- starts with the full model,
- ▶ deletes the predictor that has the least impact on the fit.

How to choose the candidate for dropping? E.g. variable  $X_j$  with the smallest absolute Z-score

$$Z_j \equiv \frac{\hat{\beta}_j}{\widehat{\mathrm{sd}}(\hat{\beta}_j)},$$

where  $\widehat{\operatorname{sd}}(\hat{\beta}_j)$  is the approx. standard error for  $\hat{\beta}_j$ 

#### Remarks

▶ Backward selection can only be used when n > p, while forward stepwise can always be used.

## Regularization: shrinkage

Idea: introducing a little bias in the estimation of  $\beta$  may lead to a substantial decrease in variance and, hence, in the true error rate

### Penalized regression

Regularize the estimation problem by introducing a penalization term for  $\beta$ 

$$\widetilde{\beta} = \arg\min_{\beta} \left[ \operatorname{RSS}(\beta) + \lambda \operatorname{Pen}(\beta) \right]$$

- ▶ RSS( $\beta$ ) is the *fidelity term* to the training set (replace with the opposite log-likehihood  $-\ell(\beta)$  for generalized linear model, e.g. logistic regression)
- $ightharpoonup \operatorname{Pen}(\beta)$  is the *a priori* to regularize the solution,
- $\lambda > 0$  is the penalization coefficient

Choosing  $\lambda$ : tradeoff between overfitting (small  $\lambda$ ) and underfitting (large  $\lambda$ )

standard practice is to use cross-validation to estimate an optimal  $\lambda$  for the test error rate (but AIC/BIC can also be used)

## Ridge regression

Penalization in the (squared)  $\ell_2$  sense:

$$\operatorname{Pen}(\beta) \equiv \beta^T \beta = ||\beta||_2^2, \leftarrow \operatorname{Tychonov regularization}$$

 $\widetilde{\beta}$  is thus obtained by minimizing

$$\begin{split} \mathrm{RSS}(\beta) + \lambda \operatorname{Pen}(\beta) &= (Y - X\beta)^T (Y - X\beta) + \lambda \beta^T \beta, \\ &= \left(\beta - (X^T X + \lambda I)^{-1} X^T Y\right)^T \left(X^T X + \lambda I\right) \left(\beta - (X^T X + \lambda I)^{-1} X^T Y\right) + \mathrm{Cst}, \end{split}$$

Ridge estimator : 
$$\tilde{\beta} = (X^T X + \lambda I)^{-1} X^T Y$$

#### Remark

similar to LS estimator, with an additional 'ridge' on the diagonal of  $\boldsymbol{X}^T\boldsymbol{X}$ 

- ▶  $X^TX + \lambda I$  has all its eigenvalues greater than  $\lambda > 0$ ,  $\leftarrow$  ensures that  $\widetilde{\beta}$  is always defined, and stable for large enough  $\lambda$
- when  $\lambda \to 0$ , then  $\widetilde{\beta} \to \widehat{\beta}$ ,
- when  $\lambda \to +\infty$ , then  $\widetilde{\beta} \to 0$

## Ridge Regression : deconvolution illustration

- $y \in \mathbb{R}^n$  with  $n = 256^2$ ,  $\beta \in \mathbb{R}^p$  with  $p = 256^2$ ,
- ▶  $X \in \mathbb{R}^{n \times p} \leftarrow \text{sized } (256^2) \times (256^2) \text{ matrix...}$

 $\beta \leftarrow \text{original image}$ 

 $y = X\beta \leftarrow \text{blurred image}$ 

## Ridge Regression : deconvolution illustration

- $y \in \mathbb{R}^n$  with  $n = 256^2$ ,  $\beta \in \mathbb{R}^p$  with  $p = 256^2$ ,
- ▶  $X \in \mathbb{R}^{n \times p} \leftarrow \text{sized } (256^2) \times (256^2) \text{ matrix...}$

 $\beta \leftarrow \text{original image}$ 

 $y = X\beta \leftarrow \text{blurred image}$ 

 $\widehat{\beta} = (X^T X)^{-1} X^T y \leftarrow \text{LS estimate}$ 

## Ridge Regression : deconvolution illustration

- $y \in \mathbb{R}^n$  with  $n = 256^2$ ,  $\beta \in \mathbb{R}^p$  with  $p = 256^2$ ,
- $X \in \mathbb{R}^{n \times p} \leftarrow \text{sized } (256^2) \times (256^2) \text{ matrix...}$

 $\beta \leftarrow \text{original image}$ 

 $\widetilde{\beta} = (X^T X + \lambda I)^{-1} X^T y \leftarrow \text{ridge estimate}$ 

 $y = X\beta \leftarrow \text{blurred image}$ 

 $\widehat{\beta} = (X^T X)^{-1} X^T y \leftarrow \text{LS estimate}$ 

## Regularization by promoting sparsity

### Sparse representations/approximations

A representation, or an approximation, is said to be sparse when most of the coefficients (in a given basis) are zero

### 'Bet on Sparsity' principle

Sparsity is a good option in high dimension!

- if the sparsity assumption does not hold, no method will be able to recover the underlying model in high dimension where  $p \approx n$  or p > n
- but if the sparsity assumption holds true, then the parameters can be efficiently estimated by a method that promotes sparsity
- Occam's razor or KISS (keep it simple, stupid) principles: same idea that simpler models are preferable than more complex ones

### Application to the regression problem

choosing a penalization function  $\text{Pen}(\beta)$  that promotes the sparsity of  $\beta$  (i.e. with many components  $\beta_j = 0$  for  $j = 1, \dots, p+1$ )  $\leftarrow$  Lasso estimator

## Lasso ('least absolute shrinkage and selection operator') estimator

#### Definition

$$\widetilde{\beta}_{\mathrm{lasso}} = \arg \min_{\beta} \left[ \mathrm{RSS}(\beta) + \lambda \, ||\beta||_1 \right],$$

where  $||\beta||_1 = \sum_{j=1}^{p+1} |\beta_j|$  is the  $\ell_1$  norm

- ▶ no analytical expression of  $\widetilde{\beta}_{lasso}$
- but convex optimization problem where very efficient numerical procedures are available to compute  $\tilde{\beta}_{\rm lasso}$

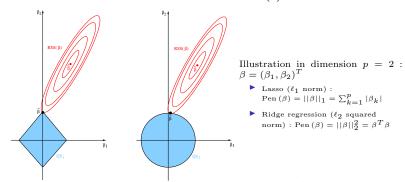

#### Lasso advantages

Converges to a generally sparse solution, i.e. such that  $\beta_k=0$  for a subset of index k

- the less significant variables are explicitly discarded
- similar stability than ridge estimator + variable selection

## Penalization with $\ell_1$ and $\ell_2$ norms : geometrical interpretation

- ▶ Least Squares estimator :  $\hat{\beta} = \arg \min RSS(\beta)$ ,
- ▶ Regularized estimator :  $\widetilde{\beta} = \arg\min \left( \text{RSS}(\beta) + \lambda \text{Pen}(\beta) \right)$  $\Leftrightarrow \widetilde{\beta} = \arg\min \ \text{RSS}(\beta) \text{ under the constraint Pen} \left( \widetilde{\beta} \right) \leq s(\lambda).$

 $\ell_1$  norm promotes the sparsity of the estimator : the less significant predictors are explicitly discarded (coeffs  $\beta_k$  are zero)  $\leftarrow$  model selection

## Application: prostate data

Stamey et al. (1989) study to examine the association between prostate specific antigen (PSA) and several clinical measures that are potentially associated with PSA in men. Objective is to predict the Log PSA from eight variables

- ▶ lcavol : Log cancer volume
- ▶ lweight : Log prostate weight
- ▶ age: The man's age
- ▶ lbph : Log of the amount of benign hyperplasia
- ▶ svi : Seminal vesicle invasion ; 1=Yes, 0=No
- ▶ lcp : Log of capsular penetration
- ▶ gleason : Gleason score
- pgg45 : Percent of Gleason scores 4 or 5

## Application: prostate data

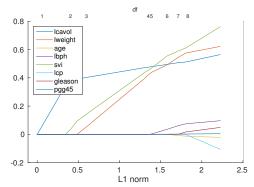

Model selection :  $\ell_1$  penalization (Lasso)

$$\widetilde{\beta}(\lambda) = \arg\min_{\beta} \mathrm{RSS}(\beta) + \lambda ||\beta||_1,$$

 $\rightarrow$  function of  $\lambda$  where less significant variables are explicitly discarded

## Path of the $\ell_1$ -penalized coefficients vs $||\widetilde{\beta}(\lambda)||_1$

### Lasso estimates path

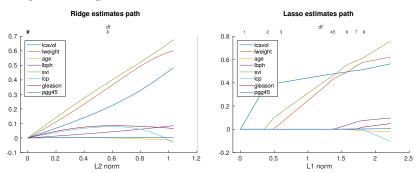

#### Choosing $\lambda$

- ▶ large  $||\tilde{\beta}(\lambda)||_1$  (small  $\lambda$ ) → overfitting
- small  $||\widetilde{\beta}(\lambda)||_1$  (large  $\lambda$ )  $\rightarrow$  underfitting
- ▶  $0.48 \le ||\tilde{\beta}(\lambda)||_1 \le 1.43$ → 3 predictors (lcavol,svi,lweight)

$$||\widetilde{\beta}(\lambda)||_1 = 1.06 \ (\lambda = 0.21)$$
 estimated by cross validation

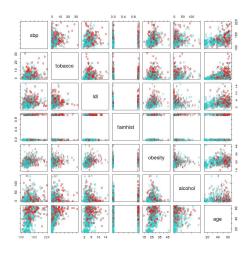

## Application: prostate data

### Comparison of ridge and lasso estimators

Path of the penalized coefficients as a function of  $||\widetilde{\beta}(\lambda)||$ 

## Application: South African coronary heart disease (CHD)

# Matrix of the predictor scatterplots

- ▶ each plot ≡ pair of risk factors
- ▶ 160 cases / 302 controls
- ▶ ldl: ~ cholesterol, sbp: systolic blood pressure

## Application: South African CHD (Cont'd)

### Logistic regression fit

	Coefficient	Std. Error	Z score
(Intercept)	-4.130	0.964	-4.285
sbp	0.006	0.006	1.023
tobacco	0.080	0.026	3.034
ldl	0.185	0.057	3.219
famhist	0.939	0.225	4.178
obesity	-0.035	0.029	-1.187
alcohol	0.001	0.004	0.136
age	0.043	0.010	4.184

 $\blacktriangleright$  A Z score (  $\equiv$  Coeff / Std. Error) > 2 in absolute value is significant at the 5% level.

### Must be interpreted with caution!

- systolic blood pressure (sbp) is not significant!
- ▶ nor is obesity (conversely, < 0 coefficient)!
- → result of the strong correlations between the predictors

Applications

Heart diseases data

## Application: South African CHD (Cont'd)

### Model selection: greedy backward procedure

Find the variables that are sufficient for explaining the CHD outputs

- drop the least significant predictor, and refit the model
- ightharpoonup repeat until no further terms can be dropped  $\leftarrow$  backward selection

### Logistic regression fit with backward model selection procedure

	Coefficient	Std. Error	Z score
(Intercept)	-4.204	0.498	-8.45
tobacco	0.081	0.026	3.16
ldl	0.168	0.054	3.09
famhist	0.924	0.223	4.14
age	0.044	0.010	4.52

### Interpretations

- ► Tobacco is measured in total lifetime usage in kilograms, with a median of 1kg for the controls and 4.1kg for the cases
- ▶ An increase of 1kg  $\Rightarrow$  increase of the CHD proba of exp (0.081) = 1.084 or 8.4% (confidence interval at 95% [1.03, 1.14])

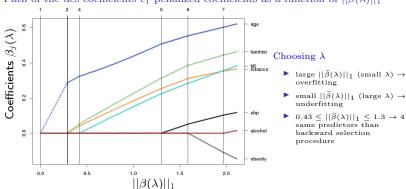

## Application: South African CHD (Cont'd)

Model selection :  $\ell_1$  penalization (Lasso type method)

$$\widetilde{\beta}(\lambda) = \arg\min_{\beta} -\ell(\beta) + \lambda ||\beta||_1,$$

 $\rightarrow$  function of  $\lambda$  where less significant variables are explicitly discarded

Path of the des coefficients  $\ell_1$ -penalized coefficients as a function of  $||\hat{\beta}(\lambda)||_1$ 

### Conclusions

#### Generalized Linear Models

Learning of the prediction rule based on a model of Y given X

Linear regression, Logistic regression

### Properties

- ► Simplicity: useful to capture the main effects
- ▶ Interpretability
- ▶ Shrinkage and Feature Selection procedures

### Perspectives (see Classification - part II)

'Black box' methods (model free) to learn the prediction rule

- Random Forests
- (Deep) Neural nets

### [Notebook]
